

Document Chunking

Document chunking is the process of splitting large documents into smaller, manageable pieces for processing. Effective chunking strategies are essential for RAG systems because chunk size affects both retrieval precision and response quality. Common approaches include fixed-size chunks with overlap, semantic splitting by headings or paragraphs, and recursive chunking that progressively divides text. The `chunk_size` parameter typically ranges from 200 to 2000 tokens, while overlap helps maintain context between chunks. Choosing the right chunking strategy depends on the document structure and use case.
