

Semantic Search

Semantic search goes beyond keyword matching to understand the meaning behind queries. Instead of looking for exact word matches, semantic search uses embeddings to find documents with similar meaning to the query. This approach handles synonyms, paraphrases, and conceptual relationships that traditional keyword search cannot capture. Semantic search works by converting both queries and documents into vector embeddings, then finding the nearest matches in the vector space. It significantly improves user experience by returning more relevant results, even when the exact search terms don't appear in the documents. Semantic search is fundamental to RAG's retrieval component.
